Q: What is the harm of taking the last number out of a cross-section? I have read some answers explaining why π -testing is almost never used to check whether a series converges (or diverges). The answers explain why it is risky to take the n th number out of a cross-section of a series, but don't explain the harm of taking the last number out. Could someone explain this? A: Consider the series $\sum_{n=1}^{\infty} (-1)^n \frac{n^2+1}{n^2+n}$. This is convergent. In fact it is even convergent in the sense of Cesaro summation. This series is in fact a convergent series; but despite that, you can consider it as almost convergent. To do so, you have to consider only the first m terms of the series to obtain a sufficient approximation to the value of the series. That is, you consider the approximation $\sum_{n=1}^{\infty} \left(-1\right)^n \frac{n^2+1}{n^2+n} = 1 - \frac{1}{4} + \frac{1}{9} - \frac{1}{16} + \frac{1}{25} - \dots$. After this consideration, the value of the series becomes $1 - \frac{3}{4} + \frac{1}{8} - \frac{1}{16} + \frac{1}{32} - \dots$, but the value of the partial sum is 0, so the series isn't convergent. But consider the m th partial sum of the series $S_m = \sum_{n=1}^{\infty} \left(-1\right)^n \frac{n^2+1}{n^2+n}$. Note that the m th partial sum is always positive. But this partial sum is not the m th term of the series, but it is the m th partial sum of the series. In fact, $\sum_{n=1}^{\infty} \left(-1\right)^n \frac{n^2+1}{n^2+n}$

## ## @param data A `corpus` object. The elements are either `character` objects, ## strings
or tables (`tbl_df`). The elements must be named with the same ## names as the input

of the `corpus` object should be used for the ## dataframe. ## ## @param bibfile Default:
`NULL`. The name of the bibtex file to build the ## dataframe from. ## ## @param

prints a progress bar. ## ## @param fun Dummy function which returns a string. This is
